Creational & Structural Design Patterns

Sergey Mechtaev

mechtaev@pku.edu.cn

School of Computer Science, Peking University

In “A Pattern Language” [1],
Christopher Alexander wrote

Each pattern describes a problem which occurs over and over again in our environment, and then describes the core of the solution to that problem, in such a way that you can use this solution a million times over...

The “Gang of Four” [2] introduced patterns for software design:

- ▶ Creational:
 - ▶ Singleton
 - ▶ Factory
 - ▶ Builder
 - ▶ ...
- ▶ Structural:
 - ▶ Adapter
 - ▶ Decorator
 - ▶ ...
- ▶ Behavioral:
 - ▶ Template Method
 - ▶ Iterator
 - ▶ Visitor
 - ▶ Observer
 - ▶ ...

Definition ([2])

Ensure a class only has one instance, and provide a global point of access to it.

Erich Gamma:

“I'am in favor of dropping Singleton. Its use is almost always a design smell”.

```
public final class Singleton {  
    private static final Singleton INSTANCE = new Singleton();  
  
    private Singleton() {}  
  
    public static Singleton getInstance(){  
        return INSTANCE;  
    }  
}
```

```
public final class Singleton {  
    private static volatile Singleton instance = null;  
  
    private Singleton() {}  
  
    public static synchronized Singleton getInstance() {  
        if (instance == null) {  
            instance = new Singleton();  
        }  
        return instance;  
    }  
}
```

```
public final class Singleton {  
    private static volatile Singleton instance = null;  
  
    private Singleton() {}  
  
    public static Singleton getInstance() {  
        if (instance == null) {  
            synchronized(Singleton.class) {  
                if (instance == null) {  
                    instance = new Singleton();  
                }  
            }  
        }  
        return instance;  
    }  
}
```

Rust does not allow directly using global mutable variables.

```
use std::sync::Mutex;

static ARRAY: Mutex<Vec<i32>> = Mutex::new(Vec::new());

fn do_a_call() {
    ARRAY.lock().unwrap().push(1);
}

fn main() {
    do_a_call();
    do_a_call();
    do_a_call();

    let array = ARRAY.lock().unwrap();
    println!("Called {} times: {:?}", array.len(), array);
    drop(array);

    *ARRAY.lock().unwrap() = vec![3, 4, 5];

    println!("New singleton object: {:?}", ARRAY.lock().unwrap());
}
```

Definition ([2])

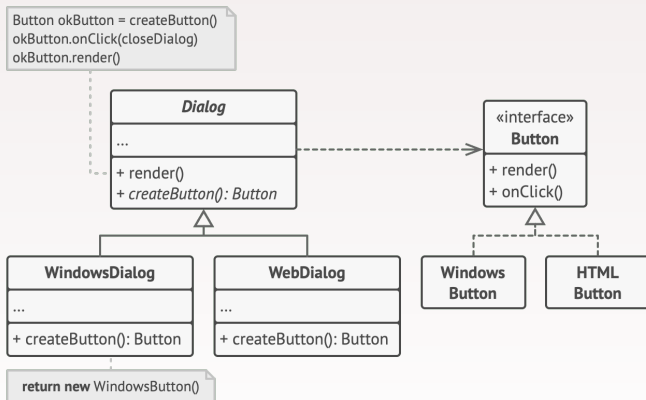

Define an interface for creating an object, but let subclasses decide which class to instantiate. Factory Method lets a class defer instantiation to subclasses.

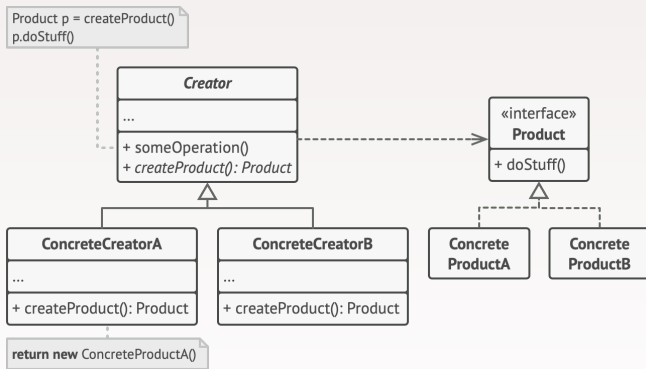

Example: different types of dialogs (Windows, Mac, HTML, etc) require their own types of elements. That's why we create a subclass for each dialog type and override their factory methods.

```
public abstract class Dialog {  
  
    public void renderWindow() {  
        // ... other code ...  
  
        Button okButton = createButton();  
        okButton.render();  
    }  
  
    public abstract Button createButton();  
}
```

Now, each dialog type will instantiate proper button classes. Base dialog works with products using their common interface, that's why its code remains functional after all changes.

```
public class HtmlDialog extends Dialog {  
  
    @Override  
    public Button createButton() {  
        return new HtmlButton();  
    }  
}
```

Definition ([2])

Separate the construction of a complex object from its representations so that the same construction process can create different representations.

In this example, the Builder pattern allows step by step construction of different car models.

```
public interface Builder {  
    void setCarType(CarType type);  
    void setSeats(int seats);  
    void setEngine(Engine engine);  
    void setTransmission(Transmission transmission);  
    void setTripComputer(TripComputer tripComputer);  
    void setGPSNavigator(GPSNavigator gpsNavigator);  
}
```

```
public class CarBuilder implements Builder {
    private CarType type;
    private int seats;
    private Engine engine;
    private Transmission transmission;
    private TripComputer tripComputer;
    private GPSNavigator gpsNavigator;

    @Override
    public void setSeats(int seats) {
        this.seats = seats;
    }

    @Override
    public void setEngine(Engine engine) {
        this.engine = engine;
    }

    ...
}
```

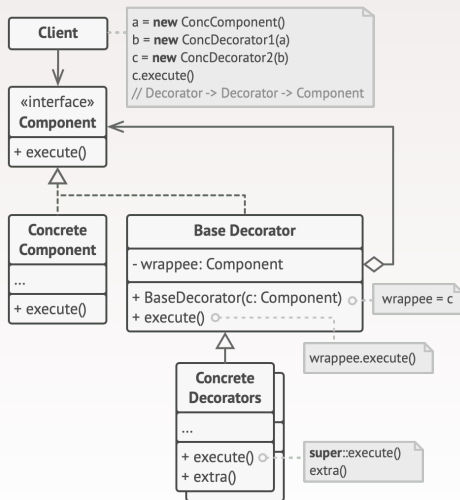

```
public class CarBuilder implements Builder {  
  
    ...  
  
    public Car getResult() {  
        return new Car(type, seats, engine, transmission, tripComputer, gpsNavigator);  
    }  
}
```

```
Command::new("git")
...
.subcommand(
    Command::new("diff")
        .about("Compare two commits")
        .arg(arg!(base: [COMMIT]))
        .arg(arg!(head: [COMMIT]))
        .arg(arg!(path: [PATH]).last(true))
        .arg(
            arg!(--color <WHEN>)
                .value_parser(["always", "auto", "never"])
                .num_args(0..=1)
                .require_equals(true)
                .default_value("auto")
                .default_missing_value("always"),
        ),
    )
```

Check examples: <https://github.com/clap-rs/clap/tree/master/examples>

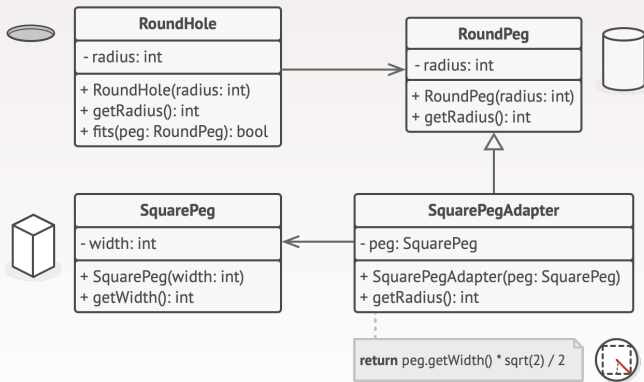

Definition ([2])

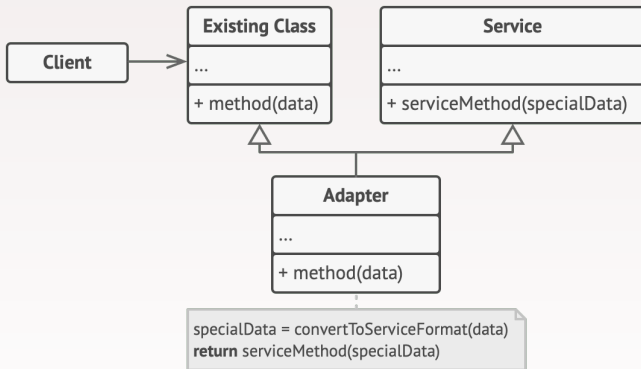

Attach additional responsibilities to an object dynamically. Decorators provide a flexible alternative to subclassing for extending functionality.

Definition ([2])

Convert the interface of a class into another interface clients expect. Adapter lets classes work together that couldn't otherwise because of incompatible interfaces.
