Property-Based Testing

Sergey Mechtaev

mechtaev@pku.edu.cn

School of Computer Science, Peking University

Parameterized tests make it possible to run a test multiple times with different arguments. An example with JUnit:

```
@ParameterizedTest
@ValueSource(strings = { "racecar", "radar", "able was I ere I saw elba" })
void palindromes(String candidate) {
    assertTrue(StringUtils.isPalindrome(candidate));
}
```

"racecar", "radar", ... are inputs, isPalindrome is a property.

Definition

Property-based testing works by testing an executable predicate (a property) on a stream of randomly generated inputs.

Popular implementations:

- ▶ QuickCheck [1] for Haskell
- Hypothesis for Python
- Proptest for Rust

Generates random integers for the argument n when testing:

```
from hypothesis import given, strategies as st

@given(st.integers())
def test_is_integer(n):
    assert isinstance(n, int)
```

assume filters out unwanted outputs:

```
from hypothesis import assume, given, strategies as st

@given(st.integers(), st.integers())
def test_floor_division_lossless_when_b_divides_a(a, b):
    assume(b != 0)
    assume(a % b == 0)
    assert (a // b) * b == a
```

Limitations of assume:

```
from hypothesis import HealthCheck, settings, assume, given, strategies
@given(st.lists(st.integers()))
@settings(suppress_health_check=[HealthCheck.filter_too_much])
def test_sort_correct(lst):
    assume(len(lst) > 3 and lst[3] == 12345)
    assert False
```

Defining custom strategies through composition:

```
from hypothesis import strategies as st

@st.composite
def sums_to_one(draw):
    1 = draw(st.lists(st.floats(0, 1)))
    return [f / sum(1) for f in 1]
```
